## CS2100 Computer Organisation Tutorial #11: Cache

(Week 13: 8 – 12 November 2021)

## **LumiNUS Discussion Question**

D1. [CS2100 AY2007/8 Semester 2 Exam Question]
A machine with a word size of 16 bits and address width of 32 bits has a **direct-mapped cache** with 16 blocks and a block size of 2 words, initially empty.

(a) Given a sequence of memory references as shown below, where each reference is given as a byte address in both decimal and hexadecimal forms, indicate whether the reference is a hit (H) or a miss (M).

Memory address		Hit (H) or Miss	(For reference)
(in decimal)	(in hexadecimal)	(M)?	(For reference)
4	0x4	M	0000 00 <mark>00 01</mark> 00
92	0x5C		0000 01 <mark>01 11</mark> 00
7	0x7		0000 00 <mark>00 01</mark> 11
146	0x92		0000 10 <mark>01 00</mark> 10
30	0x1E		0000 00 <mark>01 11</mark> 10
95	0x5F		0000 01 <mark>01 11</mark> 11
176	0xB0		0000 10 <mark>11 00</mark> 00
93	0x5D		0000 01 <mark>01 11</mark> 01
145	0x91		0000 10 <mark>01 00</mark> 01
264	0x108		0000 1 00 <mark>00 10</mark> 00
6	0x6		0000 00 <mark>00 01</mark> 10

(b) Given the above sequence of memory references, fill in the final contents of the cache. Use the notation M[i] to denote the word starting at memory address i, where i is in hexadecimal. If a block is replaced, cross out the content in the cache and write the new content over it.

## **Tutorial Questions**

1. Here is a series of address references in decimal: 4, 16, 32, 20, 80, 68, 76, 224, 36, 44, 16, 172, 20, 24, 36, and 68 in a MIPS machine. Assuming a **direct-mapped cache** with 16 oneword blocks that is initially empty, label each address reference as a hit or miss and show the content of the cache.

You may write the data word starting at memory address X as M[X]. (For example, data word starting at memory address 12 is written as M[12]. This implies that the word includes the 4 bytes of data at addresses 12, 13, 14 and 15.) You may write the tag values as decimal numbers. If a block is replaced in the cache, cross out the corresponding content in the cache, and write the new content over it.

2. Use the series of references given in question 1 above: 4, 16, 32, 20, 80, 68, 76, 224, 36, 44, 16, 172, 20, 24, 36, and 68 in a MIPS machine. Assuming a **two-way set-associative cache** with two-word blocks and a total size of 16 words that is initially empty, label each address reference as a hit or miss and show the content of the cache. Assume **LRU** replacement policy.

You may write the data word starting at memory address X as M[X]. (For example, data word starting at memory address 12 is written as M[12]. This implies that the word includes the 4 bytes of data at addresses 12, 13, 14 and 15.) You may write the tag values as decimal numbers. If a block is replaced in the cache, cross out the corresponding content in the cache, and write the new content over it.

AY2021/22 Semester 1 - 2 of 4 - CS2100 Tutorial #11

3. Although we use only data memory as example in the cache lecture, the principle covered is equally applicable to the instruction memory. This question takes a look at both the instruction cache and data cache.

The code below is from Tutorial 3 Question 1 (*palindrome checking*) with the following variable mappings:

low  $\rightarrow$  \$s0, high  $\rightarrow$  \$s1, matched  $\rightarrow$  \$s3, base of string[]  $\rightarrow$  \$s4, size  $\rightarrow$  \$s5

#	Code	Comment
i0	[some instruction]	
i1	addi \$s0, \$zero, 0	# low = 0
<b>i2</b>	addi \$s1, \$s5, -1	# high = size-1
i3	addi \$s3, \$zero, 1	<pre># matched = 1</pre>
	loop:	
<b>i4</b>	slt \$t0, \$s0, \$s1	# (low < high)?
<b>i</b> 5	beq \$t0, \$zero, exit	<pre># exit if (low &gt;= high)</pre>
<b>i6</b>	beq \$s3, \$zero, exit	<pre># exit if (matched == 0)</pre>
<b>i</b> 7	add \$t1, \$s4, \$s0	<pre># address of string[low]</pre>
<b>i8</b>	lb \$t2, 0(\$t1)	<pre># t2 = string[low]</pre>
<b>i9</b>	addi \$t3, \$s4, \$s1	<pre># address of string[high]</pre>
<b>i10</b>	lb \$t4, 0(\$t3)	<pre># t4 = string[high]</pre>
<b>i11</b>	beq \$t2, \$t4, else	
<b>i12</b>	addi \$s3, \$zero, 0	<pre># matched = 0</pre>
<b>i13</b>	j endW	# can be "j loop"
	else:	
<b>i14</b>	addi \$s0, \$s0, 1	# low++
i15	addi \$s1, \$s1, -1	# high-
	endW:	
i16	j loop	# end of while
	exit:	
i17	[some instruction]	

Parts (a) to (d) assume that instruction i0 is stored at memory address 0x0.

(a) Instruction cache: **Direct mapped with 2 blocks of 16 bytes each** (i.e. each block can hold 4 consecutive instructions).

Starting with an empty cache, the fetching of instruction i1 will cause a cache miss. After the cache miss is resolved, we now have the following instructions in the instruction cache:

Instruction Cache Block 0	[i0, <b>i1</b> , <b>i2</b> , <b>i3</b> ]
Instruction Cache Block 1	[empty]

Fetching of i2 and i3 are all cache hits as they can be found in the cache.

Assuming the string being checked is a palindrome. Show the instruction cache block content at the end of the 1<sup>st</sup> iteration (i.e. up to instruction i16).

- (b) If the loop is executed for a total of 10 iterations, what is the total number of cache hits (i.e. after the 10<sup>th</sup> "j loop" is fetched)?
- (c) Suppose we change the instruction cache to:
  - **Direct mapped with 4 blocks of 8 bytes each** (i.e. each block can hold 2 consecutive instructions).

Assuming the string being checked is a palindrome. Show the instruction cache block content at the end of the 1<sup>st</sup> iteration (i.e. up to instruction i16).

Instruction Cache Block 0	
Instruction Cache Block 1	
Instruction Cache Block 2	
Instruction Cache Block 3	

(d) If the loop is executed for a total of 10 iterations, what is the total number of cache hits (i.e. after the 10<sup>th</sup> "j loop" is fetched)?

Let us now turn to the study of **data cache**. We will assume the following scenario for parts (e) to (g):

- The string being checked is **64-character long**. The first character is located at location **0x1000**.
- The string is a palindrome (i.e. it will go through 32 iterations of the code).
- (e) Given a direct mapped data cache with 2 cache blocks, each block is 8 bytes, what is the final content of the data cache at the end of the code execution (after the code failed the beq at i5)? Use s[X..Y] to indicate the data string[X] to string[Y].

Data Cache Block #0	
Data Cache Block #1	

- (f) What is the hit rate of (e)? Give your answer in a fraction or a percentage correct to two decimal places.
- (g) Suppose the string is now **72-character long**, the first character is still located at location **0x1000** and the string is still a palindrome, what is the hit rate at the end of the execution?
